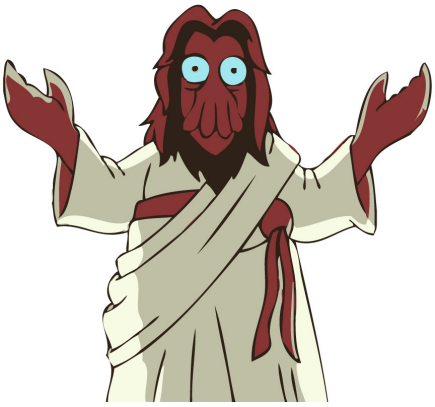
B-SYN-400

auto completion

an auto-completion engine for GPS devices



1.11

{EPITECH.}

auto completion

binary name: autoCompletion
repository name: SYN_autoCompletion_*$ACADEMICYEAR*
repository rights: ramassage-tek
language: everything working on "the dump"
compilation: via Makefile, including re, clean and fclean rules

- Your repository must contain the totality of your source files, but no useless files (binary, temp files, obj files,...).
- All the bonus files (including a potential specific Makefile) should be in a directory named *bonus*.
- Error messages have to be written on the error output, and the program should then exit with the 84 error code (0 if there is no error).

If you chose a script language, your Makefile should copy the source file and rename it with the awaited binary name.
For instance, `cp autoCompletion.py autoCompletion`

Ever since uncle Edmond's tragic car accident while he was adjusting his GPS device, the FindYourWay.com company has decided to review its address entry process.
Ever-alert to IT firms' news, you decide to propose a POC of a French address autocompletion algorithm.

Here is the algorithm:

1. the address is formatted the following way:
   `city, number streetType streetName`
   streetType can take one of the following values:
   - allée,
   - avenue,
   - boulevard,
   - chemin,
   - impasse,
   - place,
   - quai,
   - rue,
   - square
2. the autocompletion engine first looks for the city, then the street name,
3. the engine works on any part of the city's or street's name (for instance La Rochelle contains 2 parts),

4. for each letter, the engine proposes the most probable choices (5 maximum), in descending order,
5. if there is only one possibility for a letter, this one is automatically validated and the engine looks for the next one,
6. once a word is completed:
   (a) if the city is still unknwon:
      i. if only one city contains the letters sequence (as a complete word or not), this city is validated and the engine starts looking for the street name,
      ii. otherwise, the list of all the cities containing this sequence **as a complete word** is proposed in alphabetic order.
      All of the cities are associated with a number, and the user must enter the number of the correct city ; if a letter is entered instead, the propositions are reset.
   (b) if the city is already known:
      i. if only one street name contains the letters sequence (as a complete word or not), and only one address matches this city and street name, this address is proposed and the program stops,
      ii. otherwise, all the addresses matching the city and a street name that contains the sequence **as a complete word**, are proposed in alphanumeric order, each associated with a number.
      The user must enter the correct adress' number to validate it and stop the program ; if a letter is entered instead, the propostions are reset.

In case of equiprobable letters, they will be proposed in alphanumeric order.

Your program must read the address letter-by-letter on the standard input and then write the propositions made by the autocompletion engine on the standard output. It takes a dictionary as unique argument.
If ever the keyword ABORT is read, the program stops.

Terminal

```
~/B-SYN-400> ./autoCompletion -h
USAGE
     ./autoCompletion dictionary

DESCRIPTION
     dictionary    file containing one address per line, as knowledge base
```

In the dictionary, upper and lower cases must be ignored, in addition to dashes and apostrophes.
Badly-formatted addresses must be ignored as well, and printed on the error output.

The only two error messages to be printed are `Invalid argument` and `Unknown address`.

Once this first part is functionnal, implement an error-correction algorithm that rectifies badly-formattted addresses (the examples below do not show this error correction).

Obviously, only non-ambiguous addresses containing all of the needed information can be reformatted.

A good parser seems to be necessary… especially as the associated grammar is dead simple!

Your program output has to be strictly identical to the one below.

The validated letters are printed in uppercase.
The one proposed in lowercase.

Terminal

```
~/B-SYN-400> cat exampleDict
Paris, 458 boulevard Saint-Germain
Paris, 343 boulevard Saint-Germain
Marseille, 343 boulevard Camille Flammarion
Marseille, 29 rue Camille Desmoulins
